Warm-Up | The Modern Atomic Theory

Birth of the Atomic Theory

Dalton's Atomic Theory (1808):

- Elements are composed of extremely small, _____ particles called atoms.
- All atoms of an _____ are identical, and are different from the atoms of any other element.
- Atoms combine in whole number ratios to form compounds.
- _____ reactions involve the separation, combination, or rearrangement of atoms, but not the creation or destruction of atoms.

Lesson Objectives

By the end of this lesson, you should be able to:

- Describe the experimental basis for Einstein's explanation of the _____ effect.
- Explain Bohr's model of the atom and how it accounts for the existence of _____ lines.
- Describe the _____ (electron cloud) model of the atom.

Science Practice: Compare Dalton's atomic model with the current quantum model of the atom.

Words to Know

Write the letter of the definition next to the matching word as you work through the lesson. You may use the glossary to help you.

_____ electron cloud model	A. an electromagnetic radiation spectrum in which wavelengths of light emitted by a substance show up as brightly colored lines on a black background
_____ emission spectrum	B. the process in which matter emits electrons as the result of absorbing light
_____ photoelectric effect	C. the modern model of atomic structure in which protons and neutrons make up the very dense, tiny nucleus, and electrons surround the nucleus in clouds of probable locations

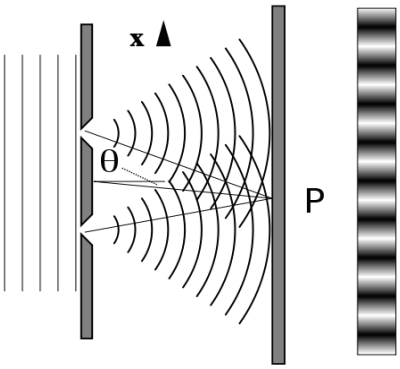
Lesson Question

Slide 2

Theories of Light

Theories of light:

- Newton (1704): _____ is made up of particles.
  - Corpuscular theory accepted until the 1800s
- Young (early 1800s): Light behaves as a _____.
  - _____ in double-slit experiment demonstrated



Light Causes Emissions

Data began to contradict the wave theory in the 1800s.

- Hertz (1887): Light shining on metal produces emissions.
  - Known as the _____
- Thomson: Particles emitted are electrons.
- Energy of electrons depends on frequency, not _____.
  - Ultraviolet light = more electrons than _____ light

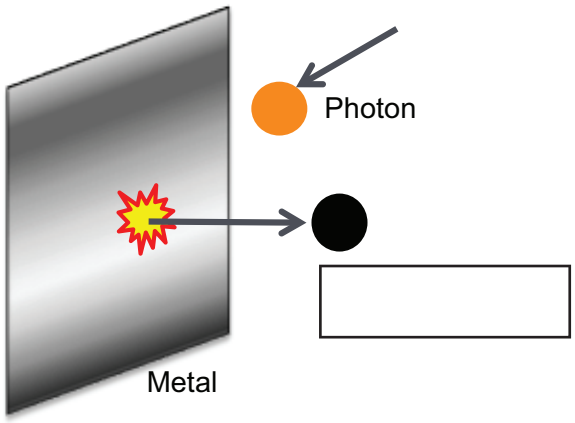
Instruction | The Modern Atomic Theory

Slide 4

Einstein and the Photoelectric Effect

Einstein's explanation of the photoelectric effect:

- Einstein: Light is a [ ] (quantum).
  - Energy of particles is [ ] (Planck).
- [ ] of quantum is given by $E = hv$.
  - E = energy
  - h = Planck's constant
  - v = frequency



Slide 7

Discrete Lines

Johannes Rydberg carried out studies on the emission spectra of heated [ ].

- [ ]: a visible light spectrum in which wavelengths of light emitted by a substance show up as bright, colored lines
- Emission spectra for some metals produced discrete lines, not continuous
- Relationship between [ ] and energy determined

Instruction | The Modern Atomic Theory

Slide 7

The Bohr Atom

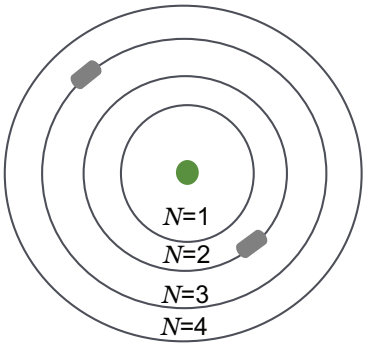
Niels Bohr (1915):

- Defined a new _____ for the atom
- Claimed electrons orbit the nucleus in discrete _____
- Created what was called the *planetary model*

The Bohr Model

In the Bohr model of the atom, only certain energy levels are permitted for the electrons.

- _____ exist in specific orbits.
- They cannot exist in other locations.
- Each orbit has a specific _____ level.
- Higher _____ have higher energies.



According to the Bohr model, an electron cannot have any possible energy. Its energy is determined by its orbit.

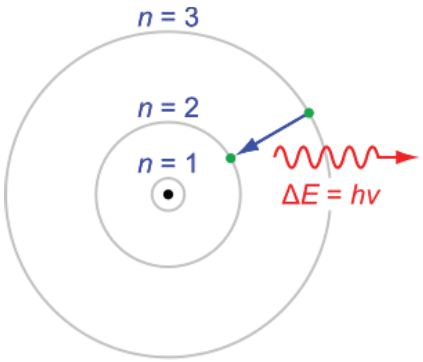
Instruction | The Modern Atomic Theory

Slide 7

Changing Energy Levels

- Electrons can absorb energy and transition to a [ ] energy level.
- The energy is emitted when the electron drops back to its original [ ].
- Each [ ] has unique energy levels.



Because orbits have specific energies, and electrons must stay in orbits, atoms can absorb or emit only specific frequencies.

Slide 10

Problems with the Bohr Model

- Some [ ] lines are brighter than others.
- The model did not work for [ ] and any larger atoms.
- Electrons have a definite radius and momentum.
- The model did not take the [ ] principle into account.

Instruction | The Modern Atomic Theory

Slide 10

Electron Cloud Model

The _____ concept was replaced by the **electron cloud model**.

- Electrons in a cloud have probable locations.
- Electron _____ have different energy levels.
- The exact position of the electron cannot be known.
- This model is the currently accepted _____ model.

Summary | The Modern Atomic Theory

Lesson Question

How was the modern understanding of the atom developed?

Answer

Slide 2

Light and the Photoelectric Effect

- Light has properties of both a _____ and a particle.
- The photoelectric effect demonstrates that light can behave as a particle.
- The energy of electrons _____ during the photoelectric effect is directly related to the energy of the light striking the metal.
- The photoelectric effect suggests that the Rutherford _____ model of the atom is not accurate.

Summary | The Modern Atomic Theory

Slide 2

The Bohr Model

- In the Bohr model, electrons orbit the nucleus in [ ] paths. They cannot exist between these orbits.
- Each orbit has specific energy.
- Electrons transitioning between energy levels [ ] or emit specific wavelengths of energy that correspond to the energy difference between the levels.
- The Bohr model cannot explain all [ ] about atoms.

The Electron Cloud Model

- The electron cloud model addresses the [ ] in the Bohr model.
- In the electron cloud model, electrons are located in clouds of probability around the nucleus.
- It is impossible to know the [ ] location of an electron within the atom.
- The electron cloud model is the currently accepted [ ] model.
